Der Unterschied der Pflanzenbestände zwischen Süd- und Nordlagen ergibt sich aus der Erhöhung der Bodenfeuchte infolge geringer Verdunstung und aus der damit verbundenen geringeren Bodenerwärmung. Erkenntlich wird er durch die Zunahme der Feuchtezeiger auf der Schattseite, zu diesen zählen alle Arten der Feucht- und Naßwiesen (Molinietalia) und der Hochstauden (Adenostylion). Bei ohnehin überfeuchteten Böden, auf denen Schwarzsegge und Kronenlattich im Borstgrasrasen vorkommen, kommt eine Änderung des Pflanzenbestandes, die auf Unterschiede in der Ex
